SMOOTH JULIA SETS OF ELLIPTIC FUNCTIONS
FOR SQUARE RHOMBIC LATTICES

JANE HAWKINS

Abstract. We discuss the dynamics of iterating the Weierstrass elliptic $\wp$ function with period lattice any real rhombic square lattice in $\mathbb{C}$, that is, a lattice generated by the complex numbers $a + ai$ and $a - ai$, $a > 0$. We conjecture that the Julia set of $\wp$ for each such lattice is the whole sphere and describe a holomorphic family of these maps. We prove the conjecture in a specific case and give results supporting it in general.

1. Introduction

Smooth Julia sets are a somewhat rare occurrence in complex dynamics and even rarer embedded in parametrized families of meromorphic maps. The only holomorphic family of rational maps with Julia set the whole sphere is due to Lattès, and a nice expository article about it may be found in [14].

In this study, we focus on one specific lattice shape for the iterated Weierstrass elliptic $\wp$ function. While this is restrictive, it is already known there is a wide variety of dynamical behavior and topology among Julia sets resulting from parametrized families of

265
elliptic functions with period lattice in the shape of a square [6], [7], [8], [9].

If the square lattice is generated by conjugate vectors of the form
\[ \lambda_1 = a + ai, \text{ and } \lambda_2 = a - ai, \]
for some real number \( a > 0 \), then we claim that there is much less variety among the Julia sets that can occur. In particular, we conjecture that in this case \( J(\wp_{\Lambda}) = \mathbb{C}_\infty \), the Riemann sphere, and we obtain a family of maps with this property, parametrized by the real parameter \( a > 0 \). The starting point for this paper is the following proposition by the author and Lorelei Koss [7].

**Proposition 1.1.** If \( \Lambda \) is a rhombic square lattice, then the Julia set is connected if and only if \( J(\wp_{\Lambda}) = \mathbb{C}_\infty \).

Our main theorem is that the condition is satisfied for one specific lattice and we conjecture that it is true for all square rhombic lattices. We give supporting evidence for the full conjecture in the form of traditional proofs and numerical evidence.

**Conjecture 1.2.** If \( \Lambda \) is a real rhombic square lattice, then \( J(\wp_{\Lambda}) = \mathbb{C}_\infty \).

The reason that the conjecture is quite difficult to prove is that there is no closed form for the Weierstrass elliptic \( \wp_{\Lambda} \) function and certainly not for any fixed or periodic points of it. We proceed by studying the classical identities for these functions and by pushing them further in order to extract dynamical results from them.

2. **Some preliminary definitions and notation**

Let \( \lambda_1, \lambda_2 \in \mathbb{C} \setminus \{0\} \) such that \( \lambda_2/\lambda_1 \notin \mathbb{R} \). We define a lattice of points in the complex plane by \( \Lambda = [\lambda_1, \lambda_2]: = \{m\lambda_1 + n\lambda_2: m, n \in \mathbb{Z}\} \). Two different sets of vectors can generate the same lattice \( \Lambda \); if \( \Lambda = [\lambda_1, \lambda_2] \), then all other generators \( \lambda_3, \lambda_4 \) of \( \Lambda \) are obtained by multiplying the vector \( (\lambda_1, \lambda_2) \) by the matrix

\[
A = \begin{pmatrix}
a & b \\
c & d
\end{pmatrix}
\]

with \( a, b, c, d \in \mathbb{Z} \) and \( ad - bc = \pm 1 \).

We can view \( \Lambda \) as a group acting on \( \mathbb{C} \) by translation, each \( \omega \in \Lambda \) inducing the transformation of \( \mathbb{C} \):
\[ T_\omega : z \mapsto z + \omega. \]

**Definition 2.1.** A closed, connected subset \( Q \) of \( \mathbb{C} \) is defined to be a *fundamental region* for \( \Lambda \) if

1. for each \( z \in \mathbb{C} \), \( Q \) contains at least one point in the same \( \Lambda \)-orbit as \( z \);
2. no two points in the interior of \( Q \) are in the same \( \Lambda \)-orbit.

If \( Q \) is any fundamental region for \( \Lambda \), then for any \( s \in \mathbb{C} \), the set

\[ Q + s = \{ z + s : z \in Q \} \]

is also a fundamental region. If we choose \( Q \) to be a parallelogram, we call \( Q \) a *period parallelogram* for \( \Lambda \).

The ratio \( \tau = \lambda_2/\lambda_1 \) is an important feature of a lattice. If \( \Lambda = [\lambda_1, \lambda_2] \) and \( k \neq 0 \) is any complex number, then \( k\Lambda \) is the lattice defined by taking \( k\lambda \) for each \( \lambda \in \Lambda \); \( k\Lambda \) is said to be *similar* to \( \Lambda \). For example, the lattice \( \Lambda_\tau = [1, \tau] \) is similar to the lattice \( \Lambda = \lambda_1\Lambda_\tau \). Similarity is an equivalence relation between lattices, and an equivalence class of lattices is called a *shape*.

**Definition 2.2.**

1. \( \Lambda = [\lambda_1, \lambda_2] \) is *real rectangular* if there exist generators such that \( \lambda_1 \) is real and \( \lambda_2 \) is purely imaginary. Any lattice similar to a real rectangular lattice is *rectangular*.
2. \( \Lambda = [\lambda_1, \lambda_2] \) is *real rhombic* if there exist generators such that \( \lambda_2 = \lambda_1 \). Any similar lattice is *rhombic*.
3. A lattice \( \Lambda \) is *square* if \( i\Lambda = \Lambda \). (Equivalently, \( \Lambda \) is square if it is similar to a lattice generated by \([\lambda, \lambda i]\), for some \( \lambda > 0 \).

In each of cases (1) – (3), the period parallelogram with vertices \( 0, \lambda_1, \lambda_2, \) and \( \lambda_3 := \lambda_1 + \lambda_2 \) can be chosen to look rectangular, rhombic, or square, respectively.

### 2.1 Real Rhombic Square Lattices

**Proposition 2.3.** The following are equivalent for a lattice \( \Lambda \).

1. \( \Lambda \) is a real rhombic square lattice.
2. There exists a \( \lambda > 0 \) such that \( \Lambda = [\lambda e^{\pi i/4}, \lambda e^{-\pi i/4}] \).
3. There exists \( \gamma > 0 \) such that \( \Lambda = [2\gamma, \gamma + i\gamma] \).
Proof: By definition, \( \Lambda \) is real rhombic square if and only if (a) \( \Lambda = [\lambda_1, \lambda_2] \) with \( \lambda_2 = \overline{\lambda_1} \) and (b) \( i\Lambda = \Lambda \).

(2) implies (1): Obviously condition (a) is satisfied, and writing \( \lambda e^{\pi i/4} \) in its Cartesian form, we have \( \Lambda = \begin{bmatrix} \lambda \sqrt{2} (1 + i) \\ \lambda \sqrt{2} (1 - i) \end{bmatrix} \). Then for any \( \omega \in \Lambda \), there exist \( m, n \in \mathbb{Z} \) such that \( \omega = m(\frac{\lambda}{\sqrt{2}} (1 + i)) + n(\frac{\lambda}{\sqrt{2}} (1 - i)) \). We have that

\[
i\omega = \text{im}(\frac{\lambda}{\sqrt{2}} (1 + i)) + \text{im}(\frac{\lambda}{\sqrt{2}} (1 - i)) = n(\frac{\lambda}{\sqrt{2}} (1 + i)) - m(\frac{\lambda}{\sqrt{2}} (1 - i)).
\]

So \( i\Lambda \subset \Lambda \); since \( \Lambda = -\Lambda = i^2\Lambda \subset i\Lambda \subset \Lambda \), (b) is satisfied.

(2) and (3) are equivalent using \( \gamma = \frac{\lambda}{\sqrt{2}} \) and changing the generator using the matrix

\[
A = \begin{pmatrix} 1 & 1 \\ 1 & 0 \end{pmatrix}.
\]

(1) implies (2): If (1) holds, then there exist generators satisfying \( \lambda_2 = \overline{\lambda_1} \); in polar form, \( \lambda_1 = re^{i\theta} \) and \( \lambda_2 = re^{-i\theta} \) for some \( \theta \in (0, \pi) \). Since, in addition, it is square, we use the remark in Definition 2.2(3) to see that \( \theta - (-\theta) = 2\theta = \pi/2 \). Therefore, \( \theta = \pi/4 \). □

We begin with \( f: \mathbb{C} \to \mathbb{C}_\infty \), a meromorphic function where \( \mathbb{C}_\infty = \mathbb{C} \cup \{\infty\} \) denotes the Riemann sphere.

**Definition 2.4.** An *elliptic function* is a meromorphic function in \( \mathbb{C} \) which is periodic with respect to a lattice \( \Lambda \).

For any \( z \in \mathbb{C} \) and any lattice \( \Lambda \), the *Weierstrass elliptic function* is defined by

\[
\wp_\Lambda(z) = \frac{1}{z^2} + \sum_{w \in \Lambda \setminus \{0\}} \left( \frac{1}{(z - w)^2} - \frac{1}{w^2} \right).
\]

Replacing every \( z \) by \( -z \) in the definition, we see that \( \wp_\Lambda \) is an even function. The map \( \wp_\Lambda \) is meromorphic, periodic with respect to \( \Lambda \), and has order 2.
The derivative of the Weierstrass elliptic function is also an elliptic function which is periodic with respect to \( \Lambda \) defined by

\[
\wp'_\Lambda(z) = -2 \sum_{w \in \Lambda} \frac{1}{(z-w)^3}.
\]

The Weierstrass elliptic function and its derivative are related by the differential equation

\[
(2.1) \quad \wp'_\Lambda(z)^2 = 4\wp\Lambda(z)^3 - g_2\wp\Lambda(z) - g_3,
\]

where \( g_2(\Lambda) = 60 \sum_{w \in \Lambda \setminus \{0\}} w^{-4} \) and \( g_3(\Lambda) = 140 \sum_{w \in \Lambda \setminus \{0\}} w^{-6} \).

The numbers \( g_2(\Lambda) \) and \( g_3(\Lambda) \) are invariants of the lattice \( \Lambda \) in the following sense: If \( g_2(\Lambda) = g_2(\Lambda') \) and \( g_3(\Lambda) = g_3(\Lambda') \), then \( \Lambda = \Lambda' \). Furthermore, given any \( g_2 \) and \( g_3 \) such that \( g_3^2 - 27g_2^3 \neq 0 \), there exists a lattice \( \Lambda \) having \( g_2 = g_2(\Lambda) \) and \( g_3 = g_3(\Lambda) \) as its invariants [5].

**Theorem 2.5** ([5]). For \( \Lambda_\tau = [1, \tau] \), the functions \( g_i(\tau) = g_i(\Lambda_\tau) \), \( i = 2, 3 \), are analytic functions of \( \tau \) in the open upper half plane \( \text{Im}(\tau) > 0 \).

We have the following homogeneity in the invariants \( g_2 \) and \( g_3 \) [8].

**Lemma 2.6.** For lattices \( \Lambda \) and \( \Lambda' \), \( \Lambda' = k\Lambda \iff g_2(\Lambda') = k^{-4}g_2(\Lambda) \) and \( g_3(\Lambda') = k^{-6}g_3(\Lambda) \).

**Theorem 2.7** ([10]). The following are equivalent:

1. \( \wp\Lambda(\bar{z}) = \wp\Lambda(z) \);
2. \( \Lambda \) is a real lattice;
3. \( g_2, g_3 \in \mathbb{R} \).

For any lattice \( \Lambda \), the Weierstrass elliptic function and its derivative satisfy the following properties: for \( k \in \mathbb{C} \setminus \{0\} \),

\[
(2.2) \quad \wp_{k\Lambda}(ku) = \frac{1}{k^2} \wp\Lambda(u), \quad \text{(homogeneity of } \wp\Lambda) \tag{2.2}
\]

\[
\wp'_{k\Lambda}(ku) = \frac{1}{k^3} \wp'_\Lambda(u), \quad \text{(homogeneity of } \wp'_\Lambda) \tag{2.2}
\]

Verification of the homogeneity properties can be seen by substitution into the series definitions.
If \( \wp'_{\Lambda}(z_0) = 0 \), then \( z_0 \) is a critical point and \( \wp_{\Lambda}(z_0) \) is a critical value. The critical values of the Weierstrass elliptic function on an arbitrary lattice \( \Lambda = [\lambda_1, \lambda_2] \) are as follows.

For \( j = 1, 2 \), notice that \( \wp_{\Lambda}(\lambda_j - z) = \wp_{\Lambda}(z) \) for all \( z \). Taking derivatives of both sides, we obtain \( -\wp'_{\Lambda}(\lambda_j - z) = \wp'_{\Lambda}(z) \). Substituting \( z = \lambda_1/2, \lambda_2/2, \) or \( \lambda_3/2 \), we see that \( \wp'_{\Lambda}(z) = 0 \) at these values. We use the notation

\[
e_1 = \wp_{\Lambda}(\frac{\lambda_1}{2}), \quad e_2 = \wp_{\Lambda}(\frac{\lambda_2}{2}), \quad e_3 = \wp_{\Lambda}(\frac{\lambda_3}{2})
\]

to denote the critical values. Since \( e_1, e_2, e_3 \) are the distinct zeros of equation (2.1), we also write

\[
(2.3) \quad \wp'_{\Lambda}(z)^2 = 4(\wp_{\Lambda}(z) - e_1)(\wp_{\Lambda}(z) - e_2)(\wp_{\Lambda}(z) - e_3).
\]

Equating like terms in equations 2.1 and 2.3, we obtain

\[
(2.4) \quad e_1 + e_2 + e_3 = 0, \quad e_1e_3 + e_2e_3 + e_1e_2 = \frac{-g_2}{4}, \quad e_1e_2e_3 = \frac{g_3}{4}.
\]

Naturally, the lattice shape relates to the properties and dynamics of the corresponding Weierstrass elliptic function. Denote

\[
(2.5) \quad p(x) = 4x^3 - g_2x - g_3,
\]

the polynomial associated with \( \Lambda \). Let \( \Delta = g_3^2 - 27g_2^3 \neq 0 \) denote its discriminant.

**Proposition 2.8** ([5]).

1. If \( \Lambda \) is real rhombic, then the discriminant is negative; in this case, the roots of \( p \) are one real and a complex conjugate pair. If \( g_3 > 0 \), then the vertical diagonal of the rhombus is longer than the horizontal diagonal, and if \( g_3 < 0 \), then the horizontal diagonal of the rhombus is longer than the vertical diagonal.

2. If \( \Lambda \) is rhombic square, then \( g_2 < 0 \) and \( g_3 = 0 \); in this case, the roots of \( p \) are \( 0, \pm \sqrt[3]{g_2/2} \).

The following corollary can be obtained using equations (2.1) and (2.4).

**Corollary 2.9.**

1. If \( \Lambda \) is rhombic, then \( e_2 = \overline{e_1} \) are the complex roots of equation (2.5), and \( e_3 \) is real. If \( g_3 > 0 \), then \( e_3 > 0 \), and if \( g_3 < 0 \), then \( e_3 < 0 \). (2) If \( \Lambda \) is rhombic square, then \( e_3 = 0 \), and \( e_1 = \sqrt[3]{g_2/2} = -e_2 \) are purely imaginary.
2.2 Fatou and Julia sets for elliptic functions

We review the basic dynamical definitions and properties for meromorphic functions which appear in [1], [2], [3], and [4]. As above, let \( f: \mathbb{C} \rightarrow \mathbb{C}_\infty \) be a meromorphic function where \( \mathbb{C}_\infty \) denotes the Riemann sphere. The Fatou set \( F(f) \) is the set of points \( z \in \mathbb{C}_\infty \) such that \( \{ f^n : n \in \mathbb{N} \} \) is defined and normal in some neighborhood of \( z \). The Julia set is the complement of the Fatou set on the sphere, \( J(f) = \mathbb{C}_\infty \setminus F(f) \). Notice that \( \mathbb{C}_\infty \setminus \bigcup_{n \geq 0} f^{-n}(\infty) \) is the largest open set where all iterates are defined. Since \( f(\mathbb{C}_\infty \setminus \bigcup_{n \geq 0} f^{-n}(\infty)) \subset \mathbb{C}_\infty \setminus \bigcup_{n \geq 0} f^{-n}(\infty) \), Montel’s theorem implies that

\[
J(f) = \bigcup_{n \geq 0} f^{-n}(\infty).
\]

Let \( \text{Crit}(f) \) denote the set of critical points of \( f \), i.e.,

\[
\text{Crit}(f) = \{ z : f'(z) = 0 \}.
\]

If \( z_0 \) is a critical point, then \( f(z_0) \) is a critical value. For each lattice, \( \wp_\Lambda \) has three critical values and no asymptotic values. The singular set \( \text{Sing}(f) \) of \( f \) is the set of critical and finite asymptotic values of \( f \) and their limit points. A function is called Class S if \( f \) has only finitely many critical and asymptotic values; for each lattice \( \Lambda \), every elliptic function with period lattice \( \Lambda \) is of Class S.

The postcritical set of \( \wp_\Lambda \) is

\[
P(\wp_\Lambda) = \bigcup_{n \geq 0} \wp_\Lambda^n(e_1 \cup e_2 \cup e_3).
\]

For a meromorphic function \( f \), a point \( z_0 \) is periodic of period \( p \) if there exists a \( p \geq 1 \) such that \( f^p(z_0) = z_0 \). We also call the set \( \{ z_0, f(z_0), \ldots, f^{p-1}(z_0) \} \) a \( p \)-cycle. The multiplier of a point \( z_0 \) of period \( p \) is the derivative \( (f^p)'(z_0) \). A periodic point \( z_0 \) is called attracting, repelling, or neutral if \( |(f^p)'(z_0)| \) is less than, greater than, or equal to 1, respectively. If \( |(f^p)'(z_0)| = 0 \), then \( z_0 \) is called a superattracting periodic point. As in the case of rational maps, the Julia set is the closure of the repelling periodic points [1].

Suppose \( U \) is a connected component of the Fatou set. We say that \( U \) is preperiodic if there exists \( n > m \geq 0 \) such that \( f^n(U) = f^m(U) \), and the minimum of \( n - m = p \) for all such \( n, m \) is the period of the cycle.
Proposition 2.10. If \( p \) is an attracting fixed point or a rationally neutral fixed point for \( \wp_\Lambda \), then the local coordinate chart for the point is completely contained in one fundamental period of \( \wp_\Lambda \) (in fact, in one half of one fundamental period).

**Proof:** This is due to the periodicity of \( \wp_\Lambda \); in each case, the local form is invertible. If we spill into another half fundamental period or region, then injectivity fails. \( \square \)

The main conjecture of this paper is that for a real rhombic square lattice \( \Lambda \), \( J(\wp_\Lambda) = \mathbb{C}_\infty \). However, the next result shows that there are many square lattices \( \Gamma \) with the property that the corresponding Weierstrass \( \wp \) function with period lattice \( \Gamma \) has a superattracting fixed point. Hence, the Julia set of \( \wp_\Lambda \) does not depend on the shape of a lattice as much as on its invariants \( g_2 \) and \( g_3 \) (see Figure 1).

![Figure 1](image.png)

**Figure 1.** One period of the Julia set for a square lattice with a superattracting fixed point

Proposition 2.11. Let \( \Lambda = [1, \tau] \) be a lattice such that the critical value \( \wp_\Lambda(1/2) = \epsilon \neq 0 \). If \( m \) is any odd integer and \( k = \sqrt[3]{2\epsilon/m} \) (taking any root), then the lattice \( \Gamma = k\Lambda \) has a superattracting fixed point at \( mk/2 \).

**Proof:** Equation (2.2) for \( \wp'_{k\Lambda} \) implies that \( k/2 \) is a critical point for \( \wp_\Gamma \). Since \( m \) is odd, periodicity implies that \( \wp_\Gamma(mk/2) = \wp_\Gamma(k/2) \). Further, the homogeneity property implies that

\[
\wp_\Gamma\left(\frac{mk}{2}\right) = \wp_\Gamma\left(\frac{k}{2}\right) = \wp_{k\Lambda}\left(\frac{k}{2}\right) = \frac{1}{k^2}\wp_\Lambda\left(\frac{1}{2}\right) = \frac{\epsilon}{k^2} = \frac{mk}{2}.
\]

\( \square \)
Julia sets for square lattices exhibit additional symmetry. The following was proved in [7].

**Theorem 2.12.** If $\Lambda$ is rectangular square or rhombic square, then $e^{\pi/2}f(\varphi_\Lambda) = J(\varphi_\Lambda)$ and $e^{\pi/2}F(\varphi_\Lambda) = F(\varphi_\Lambda)$.

**Proof:** Let $z \in F(\varphi_\Lambda)$; then by definition, $\varphi_\Lambda^n(z)$ exists and is normal for all $n$. By equation (2.2), $\varphi_\Lambda(iz) = -\varphi_\Lambda(z)$ and since $\varphi_\Lambda$ is even, we know that $\varphi_\Lambda^n(iz) = \varphi_\Lambda^n(z)$ for all $n \geq 2$. So $\varphi_\Lambda^n(iz)$ exists for all $n$. Let $U$ be a neighborhood of $z$ such that $\{\varphi_\Lambda^n(U)\}$ forms a normal family. Let $V = iU$. Repeating our argument, we have that $\varphi_\Lambda(V) = \varphi_\Lambda(iU) = -\varphi_\Lambda(U)$ and $\varphi_\Lambda^n(V) = \varphi_\Lambda^n(U)$ for all $n \geq 2$ and thus, $\{\varphi_\Lambda^n(U)\}$ forms a normal family. The proof of the converse is identical. So $z \in F(\varphi_\Lambda)$ if and only if $iz \in F(\varphi_\Lambda)$. By symmetry about the origin, $-z, -iz \in F(\varphi_\Lambda)$, and the Fatou set is symmetric with respect to rotation by $\pi/2$. □

### 2.3 Summary of properties of $\varphi_\Lambda$ when $\Lambda$ is a real rhombic square lattice

We collect the results for our setting and show the graph of $\varphi_\Lambda$ in this case (see Figure 2).

![Figure 2](image_url)

**Figure 2.** The graph of $\varphi_\Lambda$ for $\Lambda$ real rhombic square

For the rest of the paper, we assume that $\Lambda$ is a real rhombic square lattice. Most of these follow immediately from the results above; a few references are given for more detailed proofs.

1. $\Lambda = [\lambda e^{\pi i/4}, \lambda e^{-\pi i/4}]$ for some $\lambda > 0$.
2. $i\Lambda = \Lambda$, $iJ(\varphi_\Lambda) = J(\varphi_\Lambda)$, and $iF(\varphi_\Lambda) = F(\varphi_\Lambda)$.
3. $g_3 = 0$ and $g_2 < 0$. 
The connection between $\lambda$ and $g_2$ is as follows. For $k > 0$, $\Lambda' = k\Lambda$ if and only if $g_2(\Lambda') = k^{-4}g_2(\Lambda)$.

(5) $e_3 = 0$ and $e_1 = -e_2$ are purely imaginary and satisfy

$$-4e_1e_2 = g_2,$$

or equivalently,

$$e_1 = -\sqrt{g_2}/2.$$

(6) We define the standard lattice to be the unique lattice corresponding to $g_2 = -4$ and giving $e_1 = -i$ and $e_2 = i$.

(7) For the standard lattice, we have $\lambda = \gamma \approx 2.62206$, and we denote the special lattice $\Gamma = [b+bi, b-bi]$, with $b \approx 1.85407$ (see e.g., [12]). Note that $\gamma = \sqrt{2b}$.

3. The main results

As above, $\Gamma$ denotes the standard square rhombic lattice with side length $\gamma$.

**Theorem 3.1.** If we define a real rhombic square lattice $\Lambda = k\Gamma$, with $k = (2/b)^{1/3} \approx 1.02558$, then $J(\wp_{\Lambda}) = \mathbb{C}_\infty$.

Before giving a proof of the theorem, we need to recall some basic analytic properties of $\wp_{\Lambda}$ which follow from classical identities. There are formulas for the quarter period values of the Weierstrass elliptic function; we mention one which is of use in what follows. Let for each $i, j, k = 1, 2, 3$

(3.1) $d_i^2 = (e_i - e_j)(e_i - e_k) = 3e_i^2 - g_2/4$,

where we choose the square root so that

(3.2) $\wp_{\Lambda}(\lambda_i/4) = e_i + d_i$,

with $\Lambda = [\lambda_1, \lambda_2]$, and $\lambda_3 = \lambda_1 + \lambda_2$.

We use this to prove the following result (see Figure 3).

**Lemma 3.2.** If $\Lambda = [a+ai, a-ai]$, $a > 0$ is a real rhombic square lattice, then $\wp_{\Lambda}(a/2) = d_3 = \sqrt{-g_2/4}$, where $g_2$ is the invariant associated to the lattice $\Lambda$. In particular, for the standard lattice $\Gamma$, $\wp_{\Gamma}(b/2) = 1$ and $\wp'_{\Gamma}(b/2) = -2\sqrt{2}$. 

Proof: By equation (3.2), we have that $\wp_\Gamma(b/2) = \sqrt{-g_2/4} = 1$ since $e_3 = 0$. Moreover, by equation (2.1), we have that

$$(\wp'_\Gamma)^2 = 4 - g_2 = 8,$$

and since the function is decreasing at $b/2$, the result follows. □

Using the second equation in (2.2), we obtain the following corollary.

**Corollary 3.3.** For any lattice $\Lambda = k\Gamma$, $\wp'_\Lambda(a/2) = 2\sqrt{2}k^{-3}$.

The next result gives a simple one-point test for determining if $J(\wp_\Lambda) = \mathbb{C}_\infty$. In particular, it is enough to determine if the real quarter period lattice point is in $J(\wp_\Lambda)$.

**Proposition 3.4.** For any lattice $\Lambda = [a + ai, a - ai] = k\Gamma$, $\wp_\Lambda(a/2) = 1/k^2$; moreover, $J(\wp_\Lambda) = \mathbb{C}_\infty$ if and only if $a/2 \in J(\wp_\Lambda)$.

Proof: By Lemma 3.2 and equation (2.4), we have that $\wp_\Lambda(a/2) = \sqrt{-g_2/4} = ie_1$. Since for the standard lattice $e_1(\Gamma) = -i$, and for $k\Gamma$, $e_1(k\Gamma) = -i/k^2$, the result then follows, since $ie_1 = 1/k^2$.

For the second statement, we have that $J(\wp_\Lambda) \neq \mathbb{C}_\infty$ if and only if there exists a Fatou component which contains at least one critical value if and only if both $e_1$ and $e_2$ are in $F(\wp_\Lambda)$. This holds if and only if $ie_1$ and $ie_2$ are in $F(\wp_\Lambda)$, by Theorem 2.12, which, by the first statement of this proposition, holds if and only if $a/2 \in F(\wp_\Lambda)$. □
The next proof uses a crude estimate on the value of $\gamma$ from [12], namely that $\gamma > 1$, to produce one specific square rhombic lattice with all repelling fixed points.

**Proposition 3.5.** Denoting $\gamma = \sqrt{2}b$, with $b$ as above, and letting $k = (2/b)^{1/3}$, we have that using the lattice $\Lambda = k\Gamma$ gives a map such that $\varphi_\Lambda(a/2) = a/2$ and $\varphi'_\Lambda(a/2) = -\gamma = -\sqrt{2}b < -1$.

**Proof:** By Lemma 3.2, we have $\varphi_\Gamma(b/2) = 1$ and $\varphi'_\Gamma(b/2) = -2\sqrt{2}$, so using $k = (2/b)^{(1/3)}$, we have

$$\varphi_{k\Gamma}(kb/2) = \frac{1}{k^2}\varphi_\Gamma(b/2) = \frac{1}{k^2} = \left(\frac{b}{2}\right)^{(2/3)},$$

and $kb/2 = \left(\frac{b}{2}\right)^{(2/3)}$, so the quarter lattice point is fixed.

Using equation (2.2) to compute the derivative, we have

$$\varphi'_{k\Gamma}(kb/2) = 1/k^3(-2\sqrt{2}) = -b\sqrt{2} = \gamma$$
as claimed. \hfill \square

We now turn to the proof of Theorem 3.1, which follows easily from the results proved above.

**Proof of Main Theorem:** By Proposition 3.5, we have that $\varphi_\Lambda(a/2)$ is a repelling fixed point and is therefore in $J(\varphi_\Lambda)$. Then by Theorem 3.4, we have that $J(\varphi_\Lambda) = \mathbb{C}_\infty$. \hfill \square

We conjecture that for a real rhombic lattice, all fixed points of $\varphi_\Lambda$ are repelling. The next few results establish this for large enough lattices.

**Lemma 3.6.** Suppose $\Lambda = [a + ai, a - ai], a > 0$. Let $D = \{z\in \mathbb{C} : |z| < \sqrt{2}a\}$, the largest open disk centered at 0 and containing no other lattice points. Then the Laurent series for $\varphi_\Lambda(z)$, valid for $z \in D$, is

$$\varphi_\Lambda(z) = \frac{1}{z^2} + \frac{g_2}{30}z^2 + \frac{g_2^2}{2700}z^6 + \sum_{k=4}^{\infty} a_{2k}z^{2k},$$

with $a_n$ a polynomial in $g_2$.

In [7], it was shown that for a real square lattice, any nonrepelling fixed point is necessarily the smallest positive real one. In particular, a fixed point of $\varphi_\Lambda$ in our setting lies in the interval $(0, a)$, so
this is where a nonrepelling one would occur. This follows from the piecewise monotonicity of $\varphi_\Lambda$ and the fact that $\varphi'_\Lambda$ is increasing.

**Corollary 3.7.** As $a \to \infty$, $g_2 \to 0$, and the real fixed point in $z_0 \in D$ tends to 1 with $\varphi'_\Lambda(z_0) \to -2$. Therefore for values of a large enough, the smallest fixed point for $\varphi_\Lambda$ in $\mathbb{R}$ is repelling.

Proof: The function $h(z) = \frac{1}{z^2}$ has one real fixed point at $z_0 = 1$ with $h'(z_0) = -2$. Since the coefficients $g_2$ vary holomorphically with the lattice, by Lemma 2.6 the result follows.

For small lattices, the evidence is even more overwhelming that all fixed points are repelling, as is shown in Figure 4. We conclude with the observation that if all fixed points are repelling for $\varphi_\Lambda$, then either the Julia set is the whole sphere or it has a periodic cycle of period $> 1$ with derivative $\pm 1$, because the hyperbolic case is ruled out by results from [9]. Therefore, $\varphi_\Lambda$ has a disconnected Julia set with very unusual properties, which are the subject of further study by the author; we conjecture this cannot happen.
